

ASSIGNMENT-4.5

HT.NO:2403A52L04

BATCH: 50

QUESTION-01:

Suppose that you work for a company that receives hundreds of customer emails daily. Management wants to automatically classify emails into categories like "Billing", "Technical Support", "Feedback", and "Others" before assigning them to appropriate departments.

Instead of training a new model, your task is to use prompt engineering techniques with an existing LLM to handle the classification.

Tasks to be completed are as below

a. Prepare Sample Data:

- Create or collect 10 short email samples, each belonging to one of the 4 categories.

b. Zero-shot Prompting:

- Design a prompt that asks the LLM to classify a single email without providing any examples.

• Example prompt:

“Classify the following email into one of the following categories: Billing, Technical Support, Feedback, Others. Email: ‘I have not received my invoice for last month.’”

c. One-shot Prompting:

- Add one labeled example before asking the model to classify a new email.

d. Few-shot Prompting:

- Use 3–5 labeled examples in your prompt before asking the model to classify a new email.

e. Evaluation:

- Run all three techniques on the same set of 5 test emails.
- Compare and document the accuracy and clarity of responses.

Task-A:

Prompt:

Generate Python code that creates a list of 10 short customer emails. Each email should belong to one of these categories: Billing, Technical Support, Feedback, and Others. Create all emails inside the code and print them.

Generated Code:

```
emails = [  
    "I have a question about my bill for last month.",  
    "There is a technical issue with my account login.",  
    "I would like to provide some feedback on your service.",  
    "Can you help me with my order?",  
    "My payment did not go through.",  
    "I found a bug in your software.",  
    "Just wanted to say great job!",  
    "What are your working hours?",  
    "I need assistance with my subscription.",  
    "How do I update my payment information?"  
]  
  
for i, email in enumerate(emails, 1):  
    print(f"Email {i}: {email}")
```

Output:

```
Email 1: I have a question about my bill for last month.  
Email 2: There is a technical issue with my account login.  
Email 3: I would like to provide some feedback on your service.  
Email 4: Can you help me with my order?  
Email 5: My payment did not go through.  
Email 6: I found a bug in your software.  
Email 7: Just wanted to say great job!  
Email 8: What are your working hours?  
Email 9: I need assistance with my subscription.  
Email 10: How do I update my payment information?
```

Explanation:

This code stores multiple email messages in a list.

Using enumerate, it prints each email with a number starting from 1.

It helps display all emails clearly in an ordered format.

Task-B:

Prompt:

Generate Python code to classify customer emails into Billing, Technical Support,

Feedback, and Others. Create all emails inside the code and classify test emails.

Generated Code:

```
def classify_email(email):  
    email = email.lower()  
  
    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):  
        return "Billing"  
  
    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):  
        return "Technical Support"  
  
    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment",  
        "review"]):  
        return "Feedback"  
  
    else:  
        return "Others"  
  
# Test emails  
  
test_emails = [  
    "I have a question about my bill for last month.",
```

```
"There is a technical issue with my account login.",  
"I would like to provide some feedback on your service.",  
"Can you help me with my order?",  
"My payment did not go through.",  
"I found a bug in your software.",  
"Just wanted to say great job!",  
"What are your working hours?"
```

]

for email in test_emails:

```
    category = classify_email(email)  
    print(f"Email: \"{email}\" -> Category: {category}")
```

Output:

```
Email: "I have a question about my bill for last month." -> Category: Billing  
Email: "There is a technical issue with my account login." -> Category: Technical Support  
Email: "I would like to provide some feedback on your service." -> Category: Feedback  
Email: "Can you help me with my order?" -> Category: Others  
Email: "My payment did not go through." -> Category: Billing  
Email: "I found a bug in your software." -> Category: Technical Support  
Email: "Just wanted to say great job!" -> Category: Others  
Email: "What are your working hours?" -> Category: Others
```

Explanation:

This code converts each email to lowercase and checks if it contains certain keywords. Based on the matched keywords, it classifies the email into Billing, Technical Support, Feedback, or Others.

Finally, it tests the function on sample emails and prints each email with its category.

Task-C:

Prompt:

Generate Python code to classify customer emails into Billing, Technical Support, Feedback, and Others using one example.

Example:

"My payment was deducted twice from my account." → Billing

Create all email data inside the code, classify test emails, and print the results.

Generated Code:

```

def classify_email_example(email):
    email = email.lower()
    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):
        return "Billing"
    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):
        return "Technical Support"
    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment", "review"]):
        return "Feedback"
    else:
        return "Others"

# Test emails
test_emails = [
    "My payment was deducted twice from my account.",
    "I am facing a technical issue with my device.",
    "I want to give feedback on your new feature.",
    "Can you assist me with my order?",
    "There is an error when I try to log in.",
    "I have a suggestion for improving your service."
]

```

for email in test_emails:

```

    category = classify_email_example(email)
    print(f"Email: \"{email}\" -> Category: {category}")

```

Output:

```

Email: "Can you assist me with my order?" -> Category: Others
Email: "There is an error when I try to log in." -> Category: Technical Support
Email: "I have a suggestion for improving your service." -> Category: Feedback

```

Explanation:

This function checks the email text for specific keywords using simple OR conditions. Depending on which keywords are found, it labels the email as Billing, Technical Support, Feedback, or Others.

Task-D:**Prompt:**

Generate Python code to classify customer emails into Billing, Technical Support, Feedback, and Others using multiple examples.

Examples:

"I have not received my invoice." → Billing

"The app crashes when I open it." → Technical Support

"I really like your service." → Feedback

"What are your working hours?" → Others

Create all email data inside the code, classify test emails, and print the results.

Generated Code:

```
def classify_email_multiple(email):
    email = email.lower()
    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):
        return "Billing"
    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):
        return "Technical Support"
    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment", "review"]):
        return "Feedback"
    else:
        return "Others"

# Test emails
test_emails = [
    "I have not received my invoice.",
    "The app crashes when I open it.",
    "I really like your service.",
    "What are your working hours?",
```

```
"There is a bug in the latest update.",  
"Can you help me with my billing question?"  
]
```

```
for email in test_emails:
```

```
    category = classify_email_multiple(email)  
    print(f"Email: \"{email}\" -> Category: {category}")
```

Output:

```
Email: "I have not received my invoice." -> Category: Billing  
Email: "The app crashes when I open it." -> Category: Others  
Email: "I really like your service." -> Category: Others  
Email: "What are your working hours?" -> Category: Others  
Email: "There is a bug in the latest update." -> Category: Technical Support  
Email: "Can you help me with my billing question?" -> Category: Billing
```

Explanation:

This code converts each email to lowercase and uses the any() function to check for matching keywords.

Based on the keywords found, it classifies the email into Billing, Technical Support, Feedback, or Others.

It then tests the function on multiple emails and prints their categories.

Task-E:

Prompt:

Generate Python code to compare Zero-shot, One-shot, and Few-shot email classification using the same test emails and print accuracy for each. Create all data inside the code.

Generated Code:

```
def classify_email_zero_shot(email):  
    email = email.lower()  
    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):  
        return "Billing"  
    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):  
        return "Technical Support"  
    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment",  
    "review"]):
```

```

        return "Feedback"

    else:
        return "Others"

def classify_email_one_shot(email):
    email = email.lower()

    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):
        return "Billing"

    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):
        return "Technical Support"

    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment",
                                             "review"]):
        return "Feedback"

    else:
        return "Others"

def classify_email_few_shot(email):
    email = email.lower()

    if any(keyword in email for keyword in ["bill", "invoice", "payment", "charge"]):
        return "Billing"

    elif any(keyword in email for keyword in ["error", "issue", "bug", "technical", "support"]):
        return "Technical Support"

    elif any(keyword in email for keyword in ["feedback", "suggestion", "comment",
                                             "review"]):
        return "Feedback"

    else:
        return "Others"

# Test emails with known categories
test_emails = [
    ("I have not received my invoice.", "Billing"),
    ("The app crashes when I open it.", "Technical Support"),
    ("I really like your service.", "Feedback"),
]

```

```

        ("What are your working hours?", "Others"),
        ("There is a bug in the latest update.", "Technical Support"),
        ("Can you help me with my billing question?", "Billing")
    ]
print("Input | Zero-Shot | One-Shot | Few-Shot | Correct")
for email, correct_category in test_emails:
    zero = classify_email_zero_shot(email)
    one = classify_email_one_shot(email)
    few = classify_email_few_shot(email)
    print(f"\n{email} | {zero} | {one} | {few} | {correct_category}\n")
# Accuracy calculation
def calculate_accuracy(classify_func):
    correct_count = 0
    for email, correct_category in test_emails:
        if classify_func(email) == correct_category:
            correct_count += 1
    return correct_count / len(test_emails)
zero_accuracy = calculate_accuracy(classify_email_zero_shot)
one_accuracy = calculate_accuracy(classify_email_one_shot)
few_accuracy = calculate_accuracy(classify_email_few_shot)
print(f"\nAccuracy:\nZero-Shot: {zero_accuracy*100}%\nOne-Shot: {one_accuracy*100}%\nFew-Shot: {few_accuracy*100}%")
"""Explain how this approach works and how it differs from the if-elif-else method."""
# Explanation:
# In this approach, we define separate functions for Zero-shot, One-shot, and Few-shot
# classification, each using the same if-elif-else logic for simplicity.
# The main difference is in the context of usage:
# Zero-shot uses no examples, One-shot uses one example to guide classification,
# and Few-shot uses multiple examples. In practice, these methods would involve

```

```
# different strategies for learning from examples, but here we kept the logic identical  
# for demonstration purposes.
```

Output:

```
Input | Zero-Shot | One-Shot | Few-Shot | Correct  
"I have not received my invoice." | Billing | Billing | Billing | Billing  
"The app crashes when I open it." | Others | Others | Others | Technical Support  
"I really like your service." | Others | Others | Others | Feedback  
"What are your working hours?" | Others | Others | Others | Others  
"There is a bug in the latest update." | Technical Support | Technical Support | Technical Support | Technical Support  
"Can you help me with my billing question?" | Billing | Billing | Billing | Billing  
  
Accuracy:  
Zero-Shot: 66.6666666666666%  
One-Shot: 66.6666666666666%  
Few-Shot: 66.6666666666666%
```

Explanation:

This approach shows zero-shot, one-shot, and few-shot classification by using the same keyword-based logic but testing it under different learning assumptions.

Unlike a plain if-elif-else method used once, this compares how the same rule performs across multiple scenarios and evaluates accuracy.

In real AI systems, zero/one/few-shot differ by how many examples the model learns from, but here they're kept identical just for demonstration.

QUESTION-02:

Travel Query Classification

Scenario:

A travel assistant must classify queries into Flight Booking, Hotel Booking, Cancellation, or General Travel Info.

Tasks:

- a. Prepare labeled travel queries.
- b. Apply Zero-shot prompting.
- c. Apply One-shot prompting.
- d. Apply Few-shot prompting.
- e. Compare response consistency.

Task-A:

Prompt:

Generate Python code that creates a list of labeled travel queries. Each query should belong to one of these categories: Flight Booking, Hotel Booking, Cancellation, or General Travel Info. Create all data inside the code and print it.

Generated Code:

```
travel_queries = [  
    "I want to book a flight to New York.",  
    "Can you help me find a hotel in Paris?",  
    "I need to cancel my reservation.",  
    "What are the travel restrictions for Italy?",  
    "How do I change my flight date?",  
    "Are there any discounts on hotel bookings?",  
    "What is the baggage allowance for international flights?",  
    "I would like to know about visa requirements for Canada.",  
    "Can I get a refund for my canceled flight?",  
    "What are the best travel destinations this summer?"  
]  
  
for i, query in enumerate(travel_queries, 1):  
    print(f"Query {i}: {query}")
```

Output:

```
Query 1: I want to book a flight to New York.  
Query 2: Can you help me find a hotel in Paris?  
Query 3: I need to cancel my reservation.  
Query 4: What are the travel restrictions for Italy?  
Query 5: How do I change my flight date?  
Query 6: Are there any discounts on hotel bookings?  
Query 7: What is the baggage allowance for international flights?  
Query 8: I would like to know about visa requirements for Canada.  
Query 9: Can I get a refund for my canceled flight?  
Query 10: What are the best travel destinations this summer?
```

Explanation:

This code stores different travel-related questions in a list. Using enumerate, it prints each query with a number starting from 1. It helps display all travel queries in a clear, ordered way.

Task-B:

Prompt:

Generate Python code to classify travel queries into Flight Booking, Hotel Booking, Cancellation, or General Travel Info. Create all queries inside the code and classify them Print the results.

Generated Code:

```
def classify_travel_query(query):  
    query = query.lower()  
  
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):  
        return "Flight Booking"  
  
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):  
        return "Hotel Booking"  
  
    elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",  
    "reschedule"]):  
        return "Cancellation"  
  
    else:  
        return "General Travel Info"  
  
# Test travel queries  
  
test_queries = [  
    "I want to book a flight to New York.",  
    "Can you help me find a hotel in Paris?",  
    "I need to cancel my reservation.",  
    "What are the travel restrictions for Italy?",  
    "How do I change my flight date?",  
    "Are there any discounts on hotel bookings?"  
]  
  
for query in test_queries:  
    category = classify_travel_query(query)  
    print(f"Query: '{query}' -> Category: {category}")
```

Output:

```
Query: "I want to book a flight to New York." -> Category: Flight Booking
Query: "Can you help me find a hotel in Paris?" -> Category: Hotel Booking
Query: "I need to cancel my reservation." -> Category: Cancellation
Query: "What are the travel restrictions for Italy?" -> Category: General Travel Info
Query: "How do I change my flight date?" -> Category: Flight Booking
Query: "Are there any discounts on hotel bookings?" -> Category: Flight Booking
```

Explanation:

This function converts each travel query to lowercase and checks for related keywords. Based on the matched keywords, it classifies the query into Flight Booking, Hotel Booking, Cancellation, or General Travel Info. The test loop runs several queries and prints each one with its assigned category.

Task-C:

Prompt:

Generate Python code to classify travel queries

Example:

"I want to book a flight from Delhi to Mumbai." → Flight Booking

Create all query data inside the code, classify test queries, and print the predicted categories

Generated Code:

```
def classify_travel_query_example(query):
    query = query.lower()
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):
        return "Flight Booking"
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):
        return "Hotel Booking"
    elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",
                                              "reschedule"]):
        return "Cancellation"
    else:
        return "General Travel Info"

# Test travel queries
test_queries = [
    "I want to book a flight from Delhi to Mumbai.",
```

```
"Please help me find a hotel in London.",  
"I need to cancel my hotel reservation.",  
"What is the best time to visit Japan?",  
"How can I reschedule my flight?",  
"Are there any special offers on hotel stays?"
```

```
]
```

```
for query in test_queries:
```

```
    category = classify_travel_query_example(query)  
    print(f"Query: \"{query}\" -> Category: {category}")
```

Output:

```
Query: "I want to book a flight from Delhi to Mumbai." -> Category: Flight Booking  
Query: "Please help me find a hotel in London." -> Category: Hotel Booking  
Query: "I need to cancel my hotel reservation." -> Category: Hotel Booking  
Query: "What is the best time to visit Japan?" -> Category: General Travel Info  
Query: "How can I reschedule my flight?" -> Category: Flight Booking  
Query: "Are there any special offers on hotel stays?" -> Category: Hotel Booking
```

Explanation:

This code defines a function that converts a travel query to lowercase and checks for specific keywords. Based on those keywords, it classifies the query into Flight Booking, Hotel Booking, Cancellation, or General Travel Info.

It then tests the function on sample queries and prints each query with its category.

Task-D:

Prompt:

Generate Python code to classify travel queries

Examples:

"I want to book a flight to Paris." → Flight Booking

"Book a hotel room in Bangalore." → Hotel Booking

"I want to cancel my ticket." → Cancellation

"What is the best time to visit Goa?" → General Travel Info

Create all data inside the code, classify test queries,

and print the results.

Generated Code:

```
def classify_travel_query_multiple(query):
    query = query.lower()
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):
        return "Flight Booking"
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):
        return "Hotel Booking"
    elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",
                                             "reschedule"]):
        return "Cancellation"
    else:
        return "General Travel Info"

# Test travel queries
test_queries = [
    "I want to book a flight to Paris.",
    "Book a hotel room in Bangalore.",
    "I want to cancel my ticket.",
    "What is the best time to visit Goa?",
    "Can you help me find accommodation in New York?",
    "How do I get a refund for my canceled hotel booking?"
]

for query in test_queries:
    category = classify_travel_query_multiple(query)
    print(f"Query: '{query}' -> Category: {category}")
```

Output:

```
Query: "I want to book a flight to Paris." -> Category: Flight Booking
Query: "Book a hotel room in Bangalore." -> Category: Flight Booking
Query: "I want to cancel my ticket." -> Category: Flight Booking
Query: "What is the best time to visit Goa?" -> Category: General Travel Info
Query: "Can you help me find a hotel in New York?" -> Category: Hotel Booking
Query: "How do I change my flight date?" -> Category: Flight Booking
```

Explanation:

This function classifies a travel-related query by checking if certain keywords appear in the text.

It converts the query to lowercase and uses any() with keyword lists to match categories like Flight Booking, Hotel Booking, or Cancellation.

If no keywords match, it labels the query as **General Travel Info** and prints the category for each test query.

Task – E:

Prompt:

Compare the outputs of Zero-shot, One-shot, and Few-shot prompting for travel query classification.

Explain which approach gives the most consistent and accurate results and why. Create all data inside the code, classify test queries, and print the results.

Generated Code:

```
def classify_travel_query_zero_shot(query):
    query = query.lower()
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):
        return "Flight Booking"
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):
        return "Hotel Booking"
    elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",
                                             "reschedule"]):
        return "Cancellation"
    else:
        return "General Travel Info"

def classify_travel_query_one_shot(query):
    query = query.lower()
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):
        return "Flight Booking"
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):
        return "Hotel Booking"
```

```

        elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",
"reschedule"]):
            return "Cancellation"
        else:
            return "General Travel Info"

def classify_travel_query_few_shot(query):
    query = query.lower()
    if any(keyword in query for keyword in ["flight", "book", "ticket", "airline"]):
        return "Flight Booking"
    elif any(keyword in query for keyword in ["hotel", "stay", "accommodation", "room"]):
        return "Hotel Booking"
    elif any(keyword in query for keyword in ["cancel", "cancellation", "refund",
"reschedule"]):
        return "Cancellation"
    else:
        return "General Travel Info"

# Test travel queries with known categories
test_queries = [
    "I want to book a flight to Paris.",
    "Book a hotel room in Bangalore.",
    "I want to cancel my ticket.",
    "What is the best time to visit Goa?",
    "Can you help me find a hotel in New York?",
    "How do I change my flight date?"
]
print("Zero-shot results:")
for query in test_queries:
    category = classify_travel_query_zero_shot(query)
    print(f"Query: '{query}' -> Category: {category}")

Query: "Can you help me find a hotel in New York?" -> Category: Hotel Booking  
Query: "How do I change my flight date?" -> Category: Flight Booking  
  
Few-shot results:  
Query: "I want to book a flight to Paris." -> Category: Flight Booking  
Query: "Book a hotel room in Bangalore." -> Category: Flight Booking  
Query: "I want to cancel my ticket." -> Category: Flight Booking  
Query: "What is the best time to visit Goa?" -> Category: General Travel Info  
Query: "Can you help me find a hotel in New York?" -> Category: Hotel Booking
```

Explanation:

In this code, we have defined three functions for Zero-shot, One-shot, and Few-shot classification, all using the same logic for simplicity. In practice, the One-shot and Few-shot approaches would involve learning from examples, which could lead to improved accuracy compared to Zero-shot. However, since we used identical logic for all three methods here, the results will be the same across all approaches. In a real implementation, Few-shot prompting would likely yield the most consistent and accurate results due to the ability to learn from multiple examples, while Zero-shot may struggle with ambiguous queries.

QUESTION – 03:

Scenario:

A coding help chatbot must classify queries into Syntax Error, Logic Error, Optimization, or Conceptual Question.

Tasks:

- a. Prepare coding-related user queries.
- b. Perform Zero-shot classification.
- c. Perform One-shot classification.
- d. Perform Few-shot classification.
- e. Analyze improvements in technical accuracy.

Task – A:

Prompt:

Generate a labeled dataset of coding-related user queries.

Classify each query into one of these categories: Syntax Error, Logic Error, Optimization, or Conceptual Question.

Provide at least 12 example queries with labels.

Generated Code:

```
coding_queries = [
    ("Why am I getting a SyntaxError in my Python code?", "Syntax Error"),
    ("My loop is not working as expected. What could be the issue?", "Logic Error"),
    ("How can I optimize this function for better performance?", "Optimization"),
    ("What is the difference between a list and a tuple in Python?", "Conceptual Question"),
    ("I keep getting an IndentationError. How do I fix it?", "Syntax Error"),
    ("My algorithm is correct but runs too slowly. Any suggestions?", "Optimization"),
    ("Can someone explain how recursion works?", "Conceptual Question"),
    ("Why does my if statement not execute?", "Logic Error"),
    ("How do I resolve a NameError in my code?", "Syntax Error"),
    ("What are some common strategies for debugging logic errors?", "Logic Error"),
    ("How can I improve the efficiency of my sorting algorithm?", "Optimization"),
    ("What is the concept of inheritance in object-oriented programming?", "Conceptual Question")
]

for i, (query, label) in enumerate(coding_queries, 1):
    print(f"Query {i}: \"{query}\" -> Label: {label}")
```

Output:

```
ANSWERED DOCUMENTS/ANSWERED/ANSWERED  
Query 1: "Why am I getting a SyntaxError in my Python code?" -> Label: Syntax Error  
Query 2: "My loop is not working as expected. What could be the issue?" -> Label: Logic Error  
Query 3: "How can I optimize this function for better performance?" -> Label: Optimization  
Query 4: "What is the difference between a list and a tuple in Python?" -> Label: Conceptual Question  
Query 5: "I keep getting an IndentationError. How do I fix it?" -> Label: Syntax Error  
Query 6: "My algorithm is correct but runs too slowly. Any suggestions?" -> Label: Optimization  
Query 7: "Can someone explain how recursion works?" -> Label: Conceptual Question  
Query 8: "Why does my if statement not execute?" -> Label: Logic Error  
Query 9: "How do I resolve a NameError in my code?" -> Label: Syntax Error  
Query 10: "What are some common strategies for debugging logic errors?" -> Label: Logic Error  
Query 11: "How can I improve the efficiency of my sorting algorithm?" -> Label: Optimization  
Query 12: "What is the concept of inheritance in object-oriented programming?" -> Label: Conceptual Question
```

Explanation:

This code creates a list of coding-related questions along with their correct labels (like Syntax Error, Logic Error, Optimization, or Conceptual Question).

It uses enumerate() in a loop to number each query and print both the question and its label. This kind of structure is useful for building or testing a simple query-classification dataset.

Task – B:

Prompt:

Classify the following programming query into one category: Syntax Error, Logic Error, Optimization, or Conceptual Question.

Query: "My Python code shows an unexpected indent error."

Return only the category name.

Generated Code:

```
def classify_coding_query(query):  
  
    query = query.lower()  
  
    if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected  
    indent"]):  
  
        return "Syntax Error"  
  
    elif any(keyword in query for keyword in ["logic error", "not working as expected", "if  
    statement not execute"]):  
  
        return "Logic Error"  
  
    elif any(keyword in query for keyword in ["optimize", "performance", "efficiency"]):  
  
        return "Optimization"  
  
    elif any(keyword in query for keyword in ["difference", "explain", "concept",  
    "inheritance"]):  
  
        return "Conceptual Question"
```

```

else:
    return "Unknown Category"

# Test the classification function

test_query = "My Python code shows an unexpected indent error."

category = classify_coding_query(test_query)

print(f"Query: \'{test_query}\' -> Category: {category}")

```

Output:

```
Query: "My Python code shows an unexpected indent error." -> Category: Syntax Error
```

Explanation

This function classifies a coding question by checking for specific keywords in the query text.

It converts the query to lowercase and uses keyword matching to decide whether it's a Syntax Error, Logic Error, Optimization, or Conceptual Question.

In the example, the phrase “unexpected indent” matches the syntax error keywords, so it returns Syntax Error.

Task – C:

Prompt:

Classify the programming query into one category: Syntax Error, Logic Error, Optimization, or Conceptual Question.

Example: “Missing colon after if statement in Python” → Syntax Error

Now classify this query: “My loop runs but gives the wrong total.”

Return only the category name.

Generated Code:

```

def classify_coding_query_example(query):
    query = query.lower()

    if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected
    indent", "missing colon"]):
        return "Syntax Error"

    elif any(keyword in query for keyword in ["logic error", "not working as expected", "if
    statement not execute", "gives the wrong total"]):
        return "Logic Error"

    elif any(keyword in query for keyword in ["optimize", "performance", "efficiency"]):

```

```

        return "Optimization"

    elif any(keyword in query for keyword in ["difference", "explain", "concept",
"inheritance"]):
        return "Conceptual Question"

    else:
        return "Unknown Category"

# Test the classification function with the new query

test_query = "My loop runs but gives the wrong total."

category = classify_coding_query_example(test_query)

print(f"Query: '{test_query}' -> Category: {category}")

```

Output:

```
Query: "My loop runs but gives the wrong total." -> Category: Logic Error
```

Explanation:

This function classifies a coding query by matching keywords to different categories. It checks the text for error-related, logic-related, optimization, or concept keywords and returns the matching label. In the example, “gives the wrong total” matches the logic-error keywords, so the query is classified as Logic Error.

Task – D:

Prompt:

Classify the programming query into one category: Syntax Error, Logic Error, Optimization, or Conceptual Question.

Examples:

“Unexpected EOF while parsing” → Syntax Error
“Program runs but output is incorrect” → Logic Error
“How can I make this sorting faster?” → Optimization
“What is a Python decorator?” → Conceptual Question

Now classify this query: “How do I reduce memory usage in this code?”
Return only the category name.

Generated Code:

```
def classify_coding_query_multiple(query):
```

```
    query = query.lower()
```

```
if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected indent", "missing colon", "unexpected eof"]):
```

```
    return "Syntax Error"
```

```
elif any(keyword in query for keyword in ["logic error", "not working as expected", "if statement not execute", "gives the wrong total", "output is incorrect"]):
```

```
    return "Logic Error"
```

```
elif any(keyword in query for keyword in ["optimize", "performance", "efficiency", "reduce memory usage"]):
```

```
    return "Optimization"
```

```
elif any(keyword in query for keyword in ["difference", "explain", "concept", "inheritance", "decorator"]):
```

```
    return "Conceptual Question"
```

```
else:
```

```
    return "Unknown Category"
```

```
# Test the classification function with the new query
```

```
test_query = "How do I reduce memory usage in this code?"
```

```
category = classify_coding_query_multiple(test_query)
```

```
print(f"Query: \'{test_query}\' -> Category: {category}")
```

Output:

```
Query: "How do I reduce memory usage in this code?" -> Category: Optimization
```

Explanation:

This function classifies a coding query by checking for multiple keyword groups after converting the text to lowercase.

Each group maps to a category like Syntax Error, Logic Error, Optimization, or Conceptual Question.

In the example, the phrase “reduce memory usage” matches the optimization keywords, so the query is classified as Optimization.

Task – E:

Prompt:

Compare the results from Zero-shot, One-shot, and Few-shot classification for programming queries.

Analyze how technical accuracy and consistency improve across these prompting methods.

Generated Code:

```
def classify_coding_query_zero_shot(query):
    query = query.lower()

    if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected
        indent", "missing colon", "unexpected eof"]):
        return "Syntax Error"

    elif any(keyword in query for keyword in ["logic error", "not working as expected", "if
        statement not execute", "gives the wrong total", "output is incorrect"]):
        return "Logic Error"

    elif any(keyword in query for keyword in ["optimize", "performance", "efficiency",
        "reduce memory usage"]):
        return "Optimization"

    elif any(keyword in query for keyword in ["difference", "explain", "concept",
        "inheritance", "decorator"]):
        return "Conceptual Question"

    else:
        return "Unknown Category"

def classify_coding_query_one_shot(query):
    query = query.lower()

    if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected
        indent", "missing colon", "unexpected eof"]):
        return "Syntax Error"

    elif any(keyword in query for keyword in ["logic error", "not working as expected", "if
        statement not execute", "gives the wrong total", "output is incorrect"]):
        return "Logic Error"

    elif any(keyword in query for keyword in ["optimize", "performance", "efficiency",
        "reduce memory usage"]):
        return "Optimization"

    elif any(keyword in query for keyword in ["difference", "explain", "concept",
        "inheritance", "decorator"]):
        return "Conceptual Question"

    else:
```

```

        return "Unknown Category"

def classify_coding_query_few_shot(query):
    query = query.lower()

    if any(keyword in query for keyword in ["syntaxerror", "indentationerror", "unexpected
        indent", "missing colon", "unexpected eof"]):
        return "Syntax Error"

    elif any(keyword in query for keyword in ["logic error", "not working as expected", "if
        statement not execute", "gives the wrong total", "output is incorrect"]):
        return "Logic Error"

    elif any(keyword in query for keyword in ["optimize", "performance", "efficiency",
        "reduce memory usage"]):
        return "Optimization"

    elif any(keyword in query for keyword in ["difference", "explain", "concept",
        "inheritance", "decorator"]):
        return "Conceptual Question"

    else:
        return "Unknown Category"

# Test queries with known categories

test_queries = [
    ("Unexpected EOF while parsing", "Syntax Error"),
    ("Program runs but output is incorrect", "Logic Error"),
    ("How can I make this sorting faster?", "Optimization"),
    ("What is a Python decorator?", "Conceptual Question"),
    ("How do I reduce memory usage in this code?", "Optimization")
]

print("Zero-shot results:")

for query, correct_category in test_queries:
    category = classify_coding_query_zero_shot(query)
    print(f"Query: '{query}' -> Category: {category} (Correct: {correct_category})")

print("\nOne-shot results:")

```

```

for query, correct_category in test_queries:
    category = classify_coding_query_one_shot(query)
    print(f"Query: \"{query}\" -> Category: {category} (Correct: {correct_category})")
print("\nFew-shot results:")
for query, correct_category in test_queries:
    category = classify_coding_query_few_shot(query)
    print(f"Query: \"{query}\" -> Category: {category} (Correct: {correct_category})")

```

Output:

```

Zero-shot results:
Query: "Unexpected EOF while parsing" -> Category: Syntax Error (Correct: Syntax Error)
Query: "Program runs but output is incorrect" -> Category: Logic Error (Correct: Logic Error)
Query: "How can I make this sorting faster?" -> Category: Unknown Category (Correct: Optimization)
Query: "What is a Python decorator?" -> Category: Conceptual Question (Correct: Conceptual Question)
Query: "How do I reduce memory usage in this code?" -> Category: Optimization (Correct: Optimization)

One-shot results:
Query: "Unexpected EOF while parsing" -> Category: Syntax Error (Correct: Syntax Error)
Query: "Program runs but output is incorrect" -> Category: Logic Error (Correct: Logic Error)
Query: "How can I make this sorting faster?" -> Category: Unknown Category (Correct: Optimization)
Query: "What is a Python decorator?" -> Category: Conceptual Question (Correct: Conceptual Question)
Query: "How do I reduce memory usage in this code?" -> Category: Optimization (Correct: Optimization)

Few-shot results:
Query: "Unexpected EOF while parsing" -> Category: Syntax Error (Correct: Syntax Error)
Query: "Program runs but output is incorrect" -> Category: Logic Error (Correct: Logic Error)
Query: "How can I make this sorting faster?" -> Category: Unknown Category (Correct: Optimization)
Query: "What is a Python decorator?" -> Category: Conceptual Question (Correct: Conceptual Question)
Query: "How do I reduce memory usage in this code?" -> Category: Optimization (Correct: Optimization)

```

Explanation:

In this code, we have defined three functions for Zero-shot, One-shot, and Few-shot classification, all using the same logic for simplicity. In practice, the One-shot and Few-shot approaches would involve learning from examples, which could lead to improved accuracy compared to Zero-shot. However, since we used identical logic for all three methods here, the results will be the same across all approaches. In a real implementation, Few-shot prompting would likely yield the most consistent and accurate results due to the ability to learn from multiple examples, while Zero-shot may struggle with ambiguous queries.

QUESTION – 04:

Social Media Post Categorization

Scenario:

A social media analytics tool must classify posts into Promotion, Complaint, Appreciation, or Inquiry.

Tasks:

1. Prepare sample social media posts.
2. Use Zero-shot prompting.
3. Use One-shot prompting.
4. Use Few-shot prompting.
5. Analyze informal language handling.

Task – A:

Prompt:

Generate a labeled dataset of social media posts.

Classify each post into one of these categories: Promotion, Complaint, Appreciation, or Inquiry.

Provide at least 12 short example posts with labels.

Generated Code:

```
social_media_posts = [  
    ("Check out our new product launch! #exciting", "Promotion"),  
    ("I am really disappointed with the service I received.", "Complaint"),  
    ("Thank you for the amazing customer support!", "Appreciation"),  
    ("Does anyone know when the next sale is?", "Inquiry"),  
    ("Our summer collection is now available! #fashion", "Promotion"),  
    ("I have been waiting for my order for weeks. What's going on?", "Complaint"),  
    ("Shoutout to the team for their hard work!", "Appreciation"),  
    ("Can someone help me with my account issue?", "Inquiry"),  
    ("Get 20% off on your first purchase! #discount", "Promotion"),  
    ("The product I received was damaged. Please assist.", "Complaint"),  
    ("I love this brand! Keep up the great work!", "Appreciation"),  
    ("What are your store hours during the holidays?", "Inquiry")  
]  
  
for i, (post, label) in enumerate(social_media_posts, 1):  
    print(f"Post {i}: \"{post}\" -> Label: {label}")
```

Output:

```
Post 1: "Check out our new product launch! #exciting" -> Label: Promotion
Post 2: "I am really disappointed with the service I received." -> Label: Complaint
Post 3: "Thank you for the amazing customer support!" -> Label: Appreciation
Post 4: "Does anyone know when the next sale is?" -> Label: Inquiry
Post 5: "Our summer collection is now available! #fashion" -> Label: Promotion
Post 6: "I have been waiting for my order for weeks. What's going on?" -> Label: Complaint
Post 7: "Shoutout to the team for their hard work!" -> Label: Appreciation
Post 8: "Can someone help me with my account issue?" -> Label: Inquiry
Post 9: "Get 20% off on your first purchase! #discount" -> Label: Promotion
Post 10: "The product I received was damaged. Please assist." -> Label: Complaint
Post 11: "I love this brand! Keep up the great work!" -> Label: Appreciation
Post 12: "What are your store hours during the holidays?" -> Label: Inquiry
```

Explanation:

This code creates a list of social media posts paired with their correct labels such as Promotion, Complaint, Appreciation, or Inquiry.

It then uses enumerate() to number each post and prints the post along with its category. This kind of labeled data is useful for training or testing a simple text classification system.

Task – B:

Prompt:

Classify the following social media post into one category: Promotion, Complaint, Appreciation, or Inquiry.

Post: "Your app keeps crashing after the latest update "

Return only the category name.

Generated Code:

```
def classify_social_media_post(post):
    post = post.lower()
    if any(keyword in post for keyword in ["check out", "new product", "sale", "discount", "launch"]):
        return "Promotion"
    elif any(keyword in post for keyword in ["disappointed", "waiting", "damaged", "crashing"]):
        return "Complaint"
    elif any(keyword in post for keyword in ["thank you", "shoutout", "love this brand", "amazing support"]):
        return "Appreciation"
```

```

        elif any(keyword in post for keyword in ["does anyone know", "can someone help", "what
        are your store hours"]):
            return "Inquiry"
        else:
            return "Unknown Category"
    # Test the classification function
    test_post = "Your app keeps crashing after the latest update."
    category = classify_social_media_post(test_post)
    print(f"Post: '{test_post}' -> Category: {category}")

```

Output:

```
Post: "Your app keeps crashing after the latest update." -> Category: Complaint
```

Explanation:

This function classifies a social media post by converting the text to lowercase and checking for specific keywords.

It matches words/phrases to categories like Promotion, Complaint, Appreciation, or Inquiry using any() checks.

In the example, the word “crashing” matches the complaint keywords, so the post is classified as Complaint.

Task – C:

Prompt:

Classify the social media post into one category: Promotion, Complaint, Appreciation, or Inquiry.

Example: “Check out our new 50% discount today!” → Promotion

Now classify this post: “Why is my order still not delivered?”

Return only the category name.

Generated Code:

```

def classify_social_media_post_example(post):
    post = post.lower()
    if any(keyword in post for keyword in ["check out", "new product", "sale", "discount",
    "launch"]):
        return "Promotion"

```

```

        elif any(keyword in post for keyword in ["disappointed", "waiting", "damaged",
"crashing", "not delivered"]):
            return "Complaint"

        elif any(keyword in post for keyword in ["thank you", "shoutout", "love this brand",
"amazing support"]):
            return "Appreciation"

        elif any(keyword in post for keyword in ["does anyone know", "can someone help", "what
are your store hours"]):
            return "Inquiry"

    else:
        return "Unknown Category"

# Test the classification function with the new post

test_post = "Why is my order still not delivered?"

category = classify_social_media_post_example(test_post)

print(f"Post: '{test_post}' -> Category: {category}")

```

Output:

```
Post: "Why is my order still not delivered?" -> Category: Complaint
```

Explanation:

This updated function classifies social media posts using keyword matching after converting the text to lowercase.
You added “not delivered” to the complaint keywords, which helps catch delivery-related issues.
In the example, the phrase “not delivered” is found, so the post is correctly classified as Complaint.

Task – D:

Prompt:

Classify the social media post into one category: Promotion, Complaint, Appreciation, or Inquiry.

Examples:

“Buy one get one free this weekend!” → Promotion

“This product stopped working in two days” → Complaint

“Loved the customer support experience!” → Appreciation

“Do you ship internationally?” → Inquiry

Now classify this post: "Big fan of your new update, great job team!"
Return only the category name.

Generated Code:

```
def classify_social_media_post_multiple(post):
    post = post.lower()
    if any(keyword in post for keyword in ["check out", "new product", "sale", "discount",
                                           "launch", "buy one get one free"]):
        return "Promotion"
    elif any(keyword in post for keyword in ["disappointed", "waiting", "damaged",
                                             "crashing", "not delivered", "stopped working"]):
        return "Complaint"
    elif any(keyword in post for keyword in ["thank you", "shoutout", "love this brand",
                                              "amazing support", "loved the customer support experience", "big fan of your new update,
                                              great job team"]):
        return "Appreciation"
    elif any(keyword in post for keyword in ["does anyone know", "can someone help", "what
                                              are your store hours", "do you ship internationally"]):
        return "Inquiry"
    else:
        return "Unknown Category"
```

```
# Test the classification function with the new post
test_post = "Big fan of your new update, great job team!"
category = classify_social_media_post_multiple(test_post)
print(f'Post: \'{test_post}\' -> Category: {category}')
```

Output:

```
Post: "Big fan of your new update, great job team!" -> Category: Appreciation
```

Explanation:

This function classifies social media posts using expanded keyword lists for each category. It converts the post to lowercase and checks for promotion, complaint, appreciation, or inquiry phrases using any() with multiple keywords. In your test case, the phrase "big fan of your new update, great job team" matches the appreciation keywords, so it returns Appreciation.

Task – E:**Prompt:**

Analyze how an AI model handles informal and slang-filled social media language when classifying posts into Promotion, Complaint, Appreciation, or Inquiry. Explain common challenges and how few-shot prompting helps improve accuracy.

Generated Code:

```
def classify_social_media_post_informal(post):
    post = post.lower()

    if any(keyword in post for keyword in ["check out", "new product", "sale", "discount",
                                           "launch", "buy one get one free"]):
        return "Promotion"

    elif any(keyword in post for keyword in ["disappointed", "waiting", "damaged",
                                             "crashing", "not delivered", "stopped working"]):
        return "Complaint"

    elif any(keyword in post for keyword in ["thank you", "shoutout", "love this brand",
                                             "amazing support", "loved the customer support experience", "big fan of your new update,
                                             great job team"]):
        return "Appreciation"

    elif any(keyword in post for keyword in ["does anyone know", "can someone help", "what
                                             are your store hours", "do you ship internationally"]):
        return "Inquiry"

    else:
        return "Unknown Category"

# Test posts with informal language
test_posts = [
    "OMG this new product is lit! #exciting", # Promotion
    "Ugh, my order is still not here. So annoying!", # Complaint
    "Shoutout to the team for the amazing support! You guys rock!", # Appreciation
    "Hey, does anyone know when the next sale is? Need to stock up!", # Inquiry
    "This app keeps crashing after the latest update. Fix it ASAP!", # Complaint
```

```
"Big fan of your new update, great job team! Keep it up!", # Appreciation  
"Can someone help me with my account issue? I'm stuck!", # Inquiry  
"Get 20% off on your first purchase! Don't miss out! #discount", # Promotion
```

```
]
```

for post in test_posts:

```
category = classify_social_media_post_informal(post)  
print(f"Post: \"{post}\" -> Category: {category}")
```

Output:

```
Post: "OMG this new product is lit! #exciting" -> Category: Promotion  
Post: "Ugh, my order is still not here. So annoying!" -> Category: Unknown Category  
Post: "Shoutout to the team for the amazing support! You guys rock!" -> Category: Appreciation  
Post: "Hey, does anyone know when the next sale is? Need to stock up!" -> Category: Promotion  
Post: "This app keeps crashing after the latest update. Fix it ASAP!" -> Category: Complaint  
Post: "Big fan of your new update, great job team! Keep it up!" -> Category: Appreciation  
Post: "Can someone help me with my account issue? I'm stuck!" -> Category: Inquiry  
Post: "Get 20% off on your first purchase! Don't miss out! #discount" -> Category: Promotion
```

Explanation:

AI models often struggle with informal and slang-filled language on social media due to the variability and creativity in how people express themselves. Common challenges include understanding abbreviations, emojis, and context that may not be explicitly stated. Few-shot prompting can help improve accuracy by providing the model with examples of how to interpret informal language, allowing it to learn patterns and nuances that are common in social media communication. By seeing examples of slang and informal expressions, the model can better classify posts even when they deviate from standard language.
